Meteorological Satellite Studies

*What are NearCasts?*

*How can NearCasts be used to improve  
forecaster awareness and reduce false alarms?*

*Can SEVIRI sounder data be incorporated to improve short-  
range forecasts of the Pre-Convection Environment  
over Europe/Africa?*

Ralph Petersen<sup>1</sup>, Robert M Aune<sup>2</sup> and Bill Line<sup>1</sup>

<sup>1</sup> Cooperative Institute for Meteorological Satellite Studies (CIMSS), University of Wisconsin – Madison, Madison, Wisconsin ( [Ralph.Petersen@ssec.wisc.edu](mailto:Ralph.Petersen@ssec.wisc.edu) and [Bill.Line@ssec.wisc.edu](mailto:Bill.Line@ssec.wisc.edu) )

<sup>2</sup> NOAA/NESDIS/ORA, Advanced Satellite Products Team, Madison, Wisconsin ( [Robert.Aune@noaa.gov](mailto:Robert.Aune@noaa.gov) )

*Improving the utility of GOES products  
in operational forecasting*

## *What are we trying to improve?*

*Short-range forecasts of timing and locations of severe thunderstorms  
- especially hard-to-forecast, isolated summer-time convection*

## *What are NearCasts?*

NearCasts are 1-9 hour forecasts specifically designed to monitor conditions where hazardous weather will (or will not) form.

*NearCasts* are designed:

- *to be available within minutes of observation times,*
- *to be frequently updated (hourly or sub-hourly), and*
- *to rely on observations more than traditional NWP products*

GOES NearCasts use high-density observations of moisture and humidity made over land from the GOES sounder.

*These data are not included in any operational NWP system*

## *What are we trying to improve?*

*Short-range forecasts of timing and locations of severe thunderstorms*

*- especially hard-to-forecast, isolated summer-time convection*

## *What are we trying to correct?*

- *Poor precipitation forecast accuracy in short-range NWP (esp. in summer)*

- *Under-utilization of GEO satellite moisture information over land in NWP*

- *Time lags in getting NWP guidance to forecasters*

- *Excessive smoothing of mesoscale moisture patterns*  
*in NWP data assimilation*

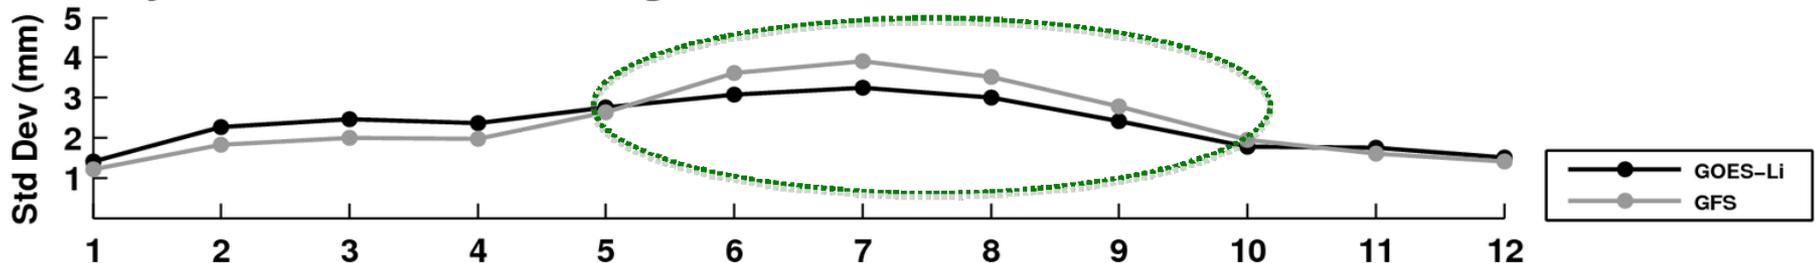

- *Loss of Infra-Red (IR) satellite information about the convective environment after convection has begun*

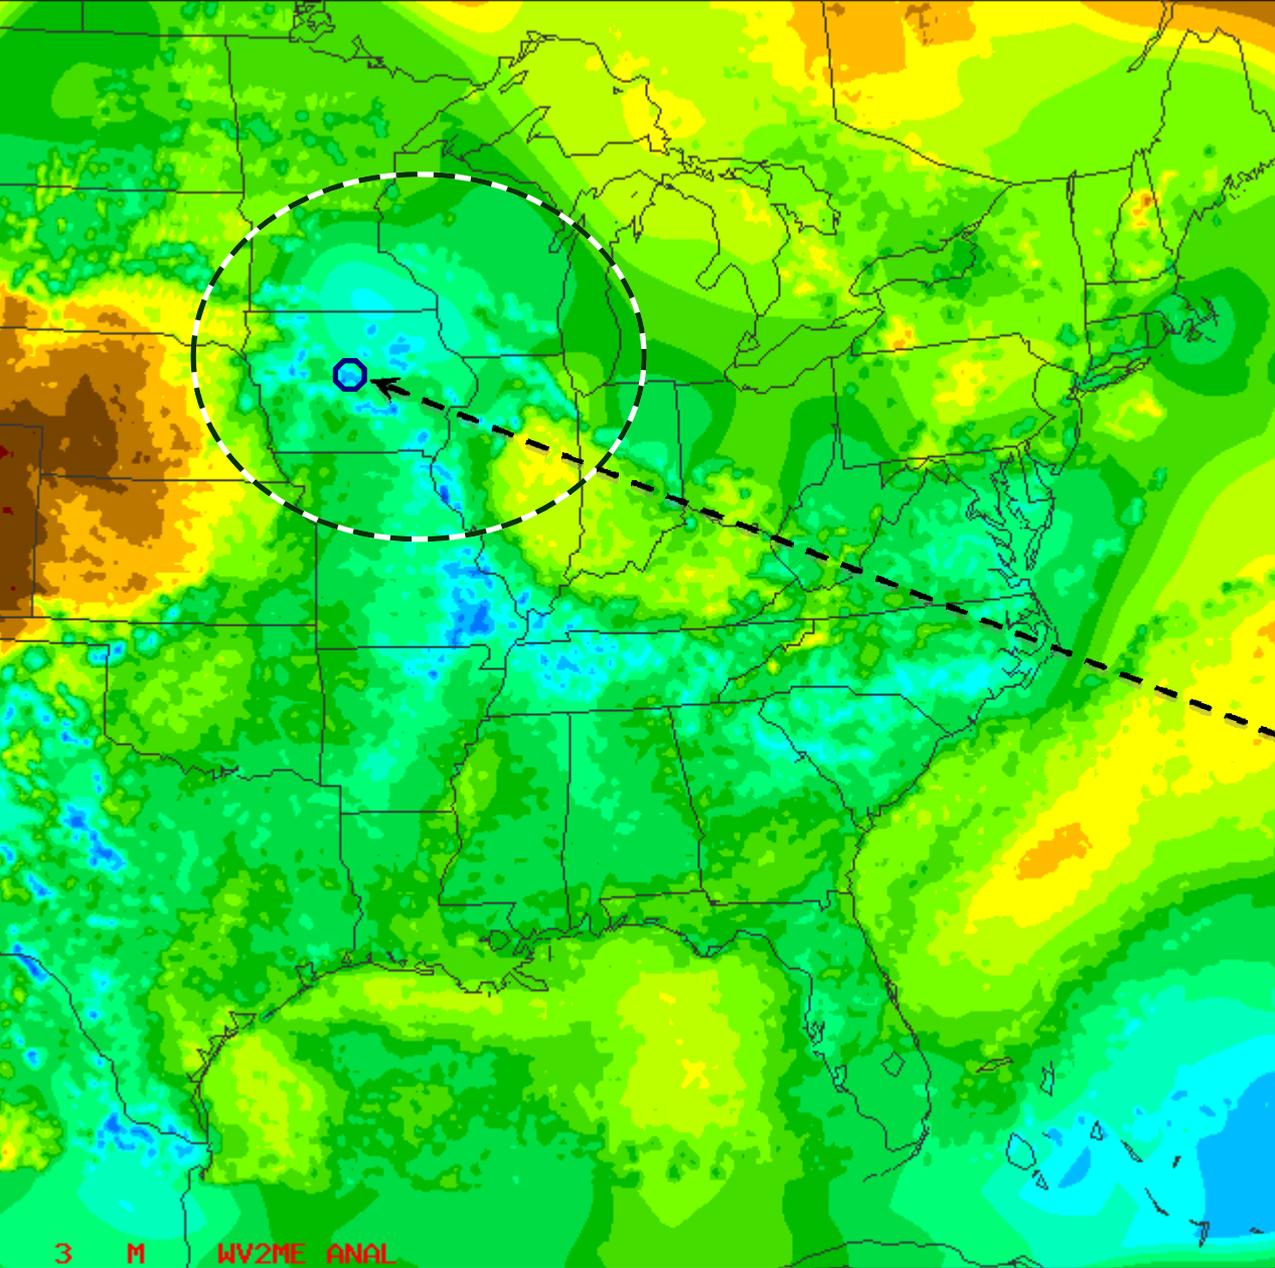

- *Need objective, observation-based tools for forecastersto use in detecting and monitoring the pre-convective environments 1-9 hours in advance*

# Evaluation of GOES Precipitable Water Retrievals (Using NCEP GFS for First Guess)

- Comparisons against GPS TPW observations around the US show:
- GOES TPW (Li retrievals) data have a wet bias
  - Worst at time of day when GFS has highest precipitation bias
- GOES TPW data show greatest improvement over First Guess:
  - 1) In warm months (*when NWP precipitation skill is worst*) and
  - 2) Using 06Z, **12Z** and 18Z GFS guess fields

Monthly GOES-Li and Background GFS TPW Initialized @ 12Z v. GPS

# Lagrangian NearCast

## How it works:

*Consider how a 3-hour NearCast is made for an observation over Iowa*

*Instead of interpolating randomly spaced moisture observations to a fixed grid (and smooth data) as done in convectional NWP, the Lagrangian approach interpolates winds to every moisture observation.*

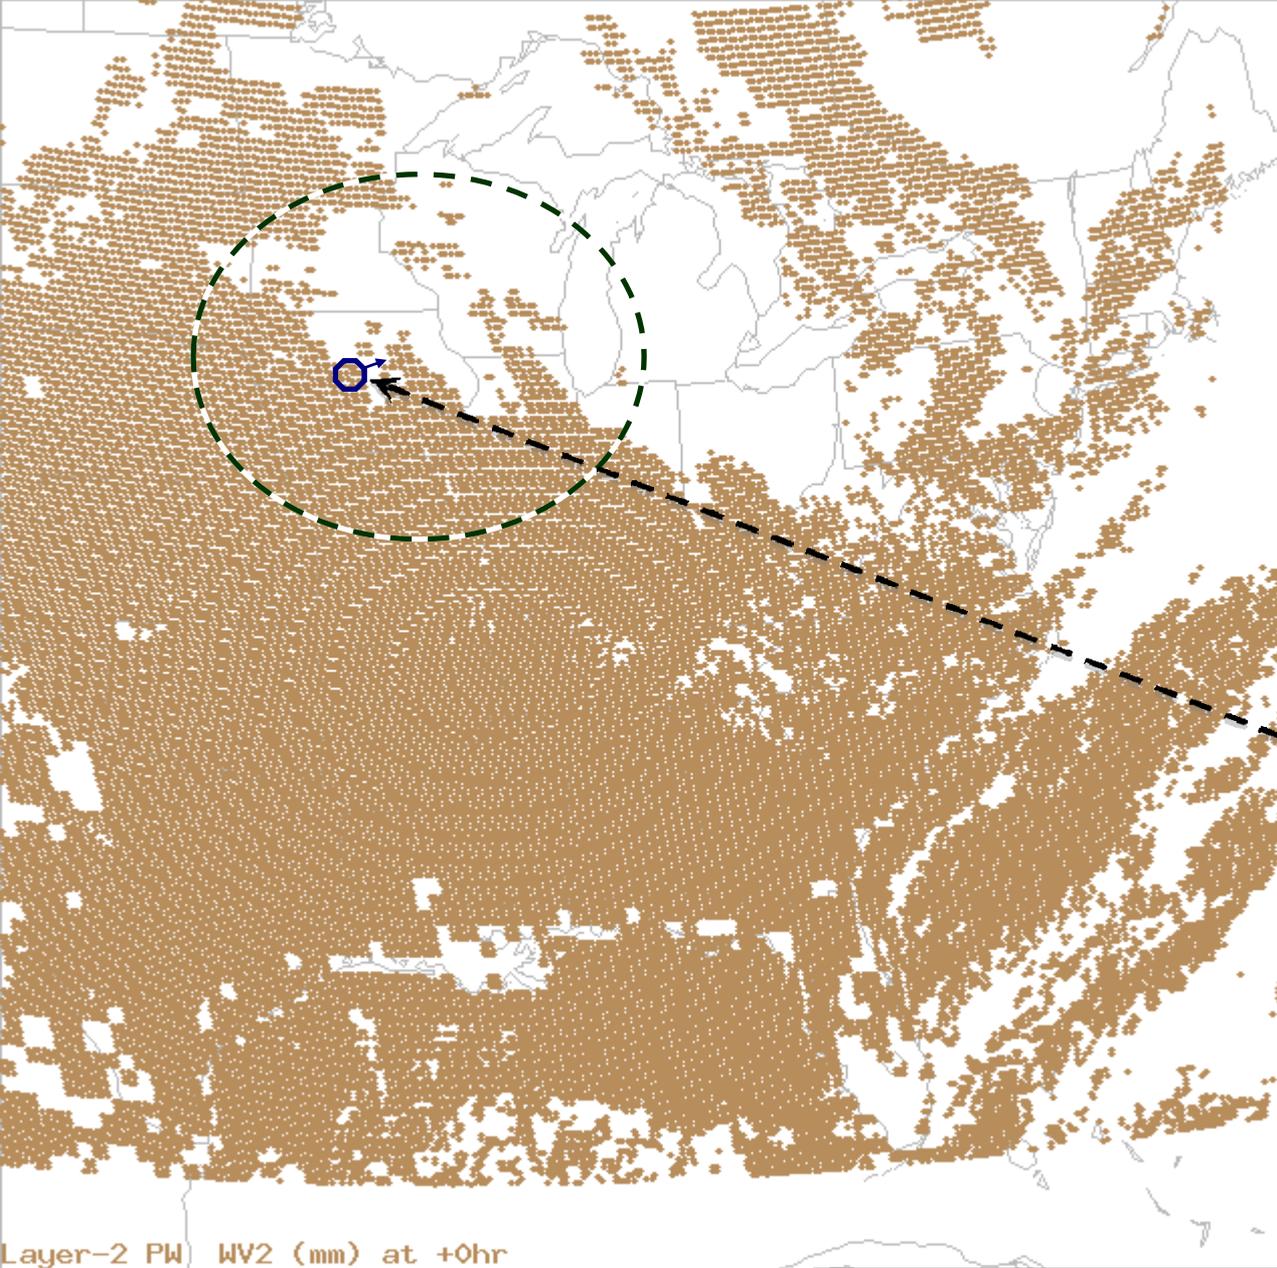

13 April 2006 – 2100 UTC

## **Lagrangian NearCast** How it works:

*Consider how a 3-hour NearCast is made for an observation over Iowa*

*Instead of interpolating randomly spaced moisture observations to a fixed grid (and smooth data) as done in convectional NWP, the Lagrangian approach interpolates winds to every moisture observation.*

*The 10 km data are then moved to new locations, using dynamically changing wind forecasts using 'long' (10-15 min.) time steps*

*The full set of 'moved' moisture observations are then interpolated to an "image grid" for display.*

**10 km data, 10 minute time steps**

13 April 2006 – 2100 UTC  
900-700 hPa GOES PW  
3 Hour NearCast Image

*The following examples demonstrates:*

*-The ability of the NearCasts using data from multiple successive observation times to improve data coverage*

*-The advantage of using Equivalent Potential Temperature ( $\theta_e$ ) both:*

*1) To monitor lower-level moisture sources and*

*2) To define Convective Destabilization more completely*

*NearCasts are useful in defining where and when convection will and will not occur*

# NearCast Analysis using only one "On-time" data set

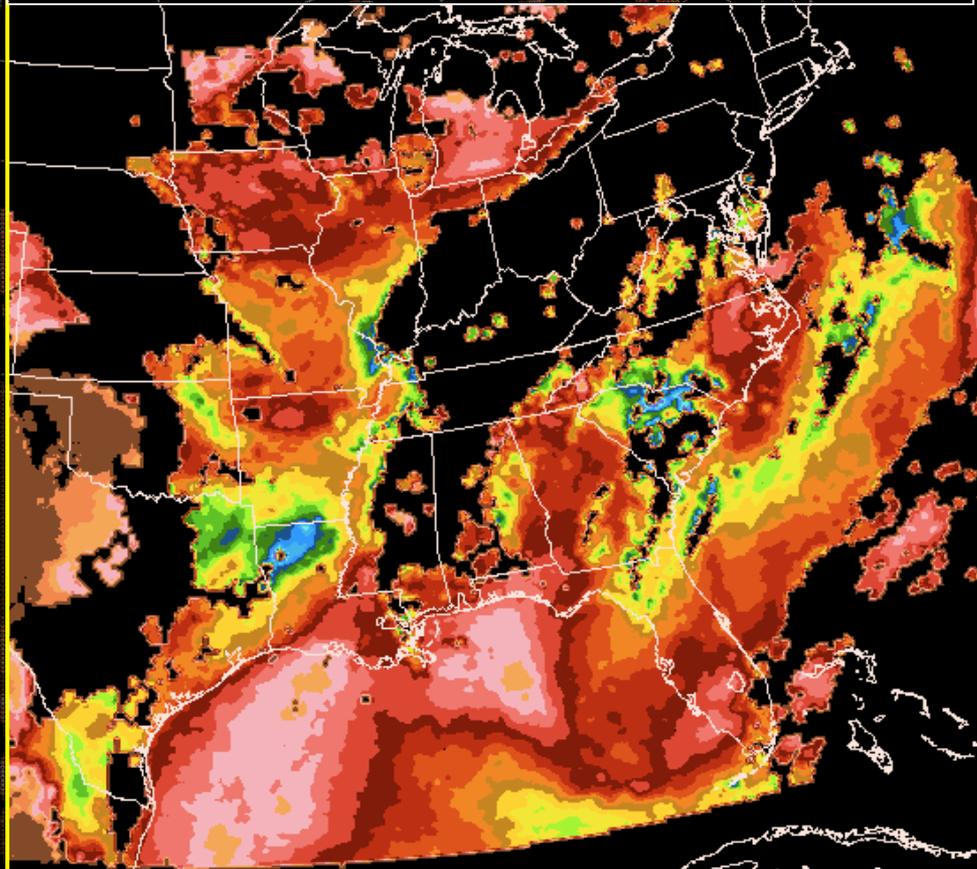

110524/1300V090 NEARCAST LAYER PRECIPITABLE WATER 900-700 MB (MM) - DOC/NOAA/NESDIS/ORA/ASPE/CISS/1

Increasing data coverage in satellite product displays

## Impact of NearCast Analysis Cycling

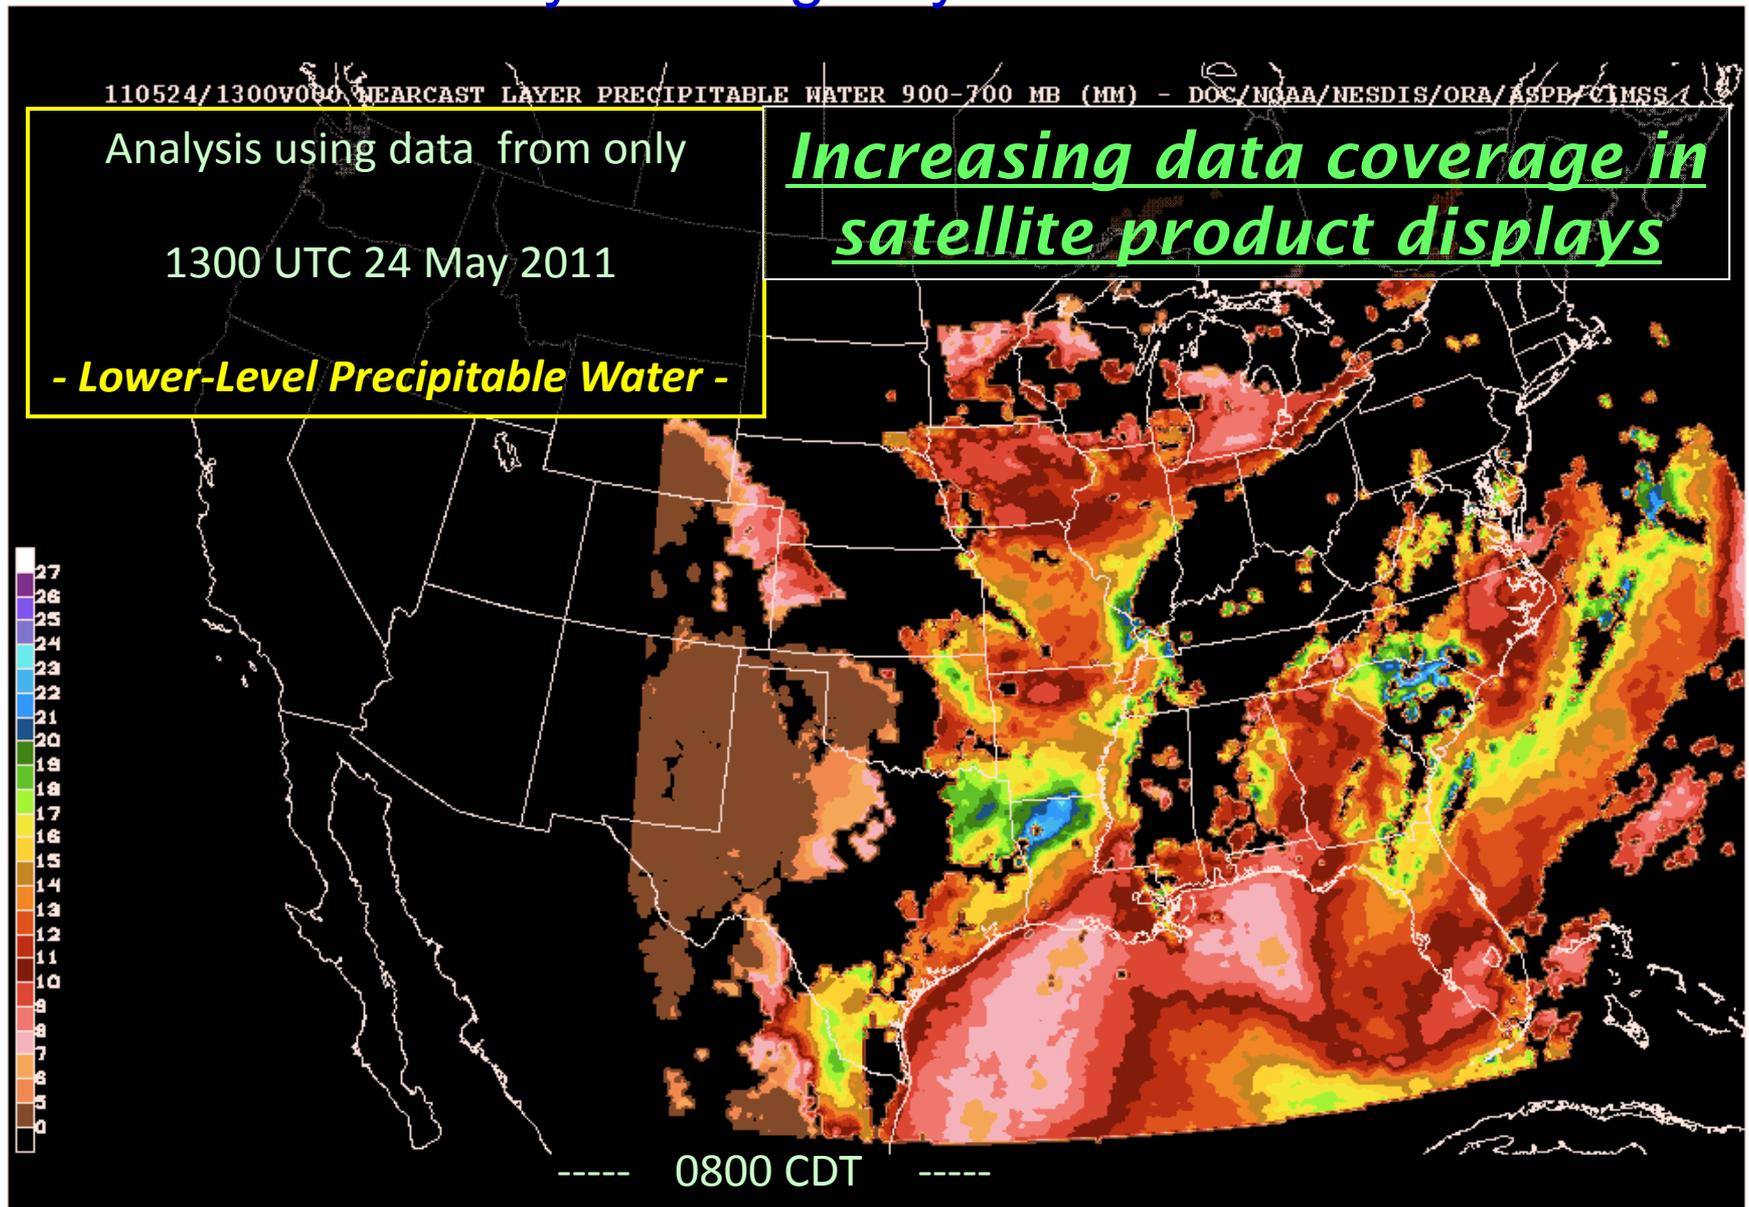

Combining:

- 1) Current Observations
- with**
- 2) Past Data at predicted locations

Lower-level Moisture Analyses using only one set of GOES sounder observations (1300UTC) contain substantial data voids

# NearCast Analysis using only one "On-time" data set

Lower-level Moisture Analyses using only one set of GOES sounder observations (1300UTC) contain substantial data voids

# NearCast Analysis using “On-time” + 1 previous data sets

110524/1400V090 NEARCAST LAYER PRECIPITABLE WATER 900-700 MB (MM) - DOC/NOAA/NESDIS/ORA/ASPE/CIMSS/1

Impact of including trajectories  
from 2 successive sets  
of hourly observations  
on areal data coverage

**- Lower-Level Precipitable Water -**

**Increasing data coverage in  
satellite product displays**

**Every hour, new  
observations are  
merged with  
trajectories of up to 9  
hours of past  
observation valid at  
the same time**

----- 0900 CDT -----

Analyses that combine projected “pseudo-observations” from 1300UTC with new GOES sounder observations at 1400UTC reduces data voids

# NearCast Analysis using "On-time" + 2 previous data sets

110524/1500V090 NEARCAST LAYER PRECIPITABLE WATER 900-700 MB (MM) - DOC/NOAA/NESDIS/ORA/ASPE/CISS/1

Impact of including trajectories  
from 3 successive sets  
of hourly observations  
on areal data coverage

**- Lower-Level Precipitable Water -**

**Increasing data coverage in  
satellite product displays**

**Every hour, new  
observations are  
merged with  
trajectories of up to 9  
hours of past  
observation valid at  
the same time**

----- 1000 CDT -----

Analyses that combine "pseudo-observations" from 1300 and 1400 UTC with GOES sounder observations at 1500UTC further reduces data voids

# NearCast Analysis using "On-time" + 9 previous data sets

110524/2200V090 NEARCAST LAYER PRECIPITABLE WATER 900-700 MB (MM) - DOC/NOAA/NESDIS/ORA/ASPB/CISS/1

Impact of including trajectories  
from 10 successive sets  
of hourly observations  
on areal data coverage

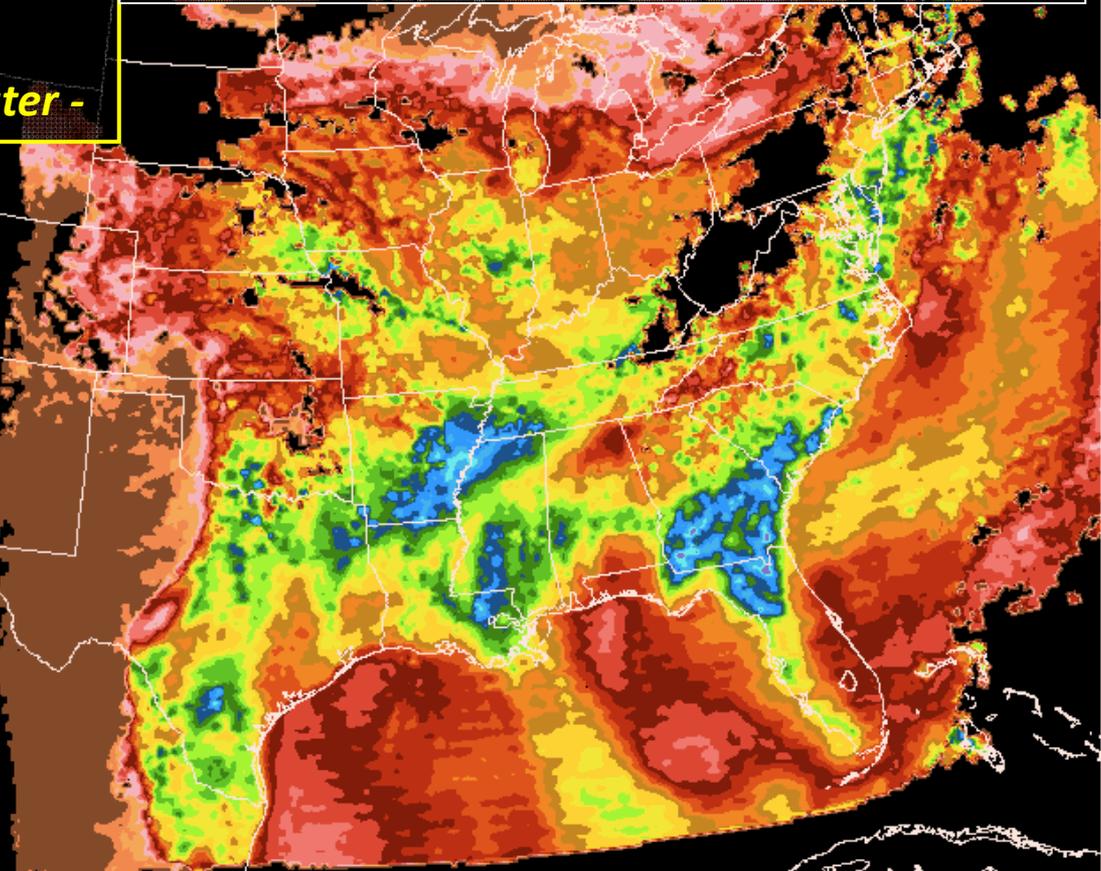

**- Lower-Level Precipitable Water -**

**Increasing data coverage in  
satellite product displays**

**Every hour, new  
observations are  
merged with  
trajectories of up to 9  
hours of past  
observation valid at  
the same time**

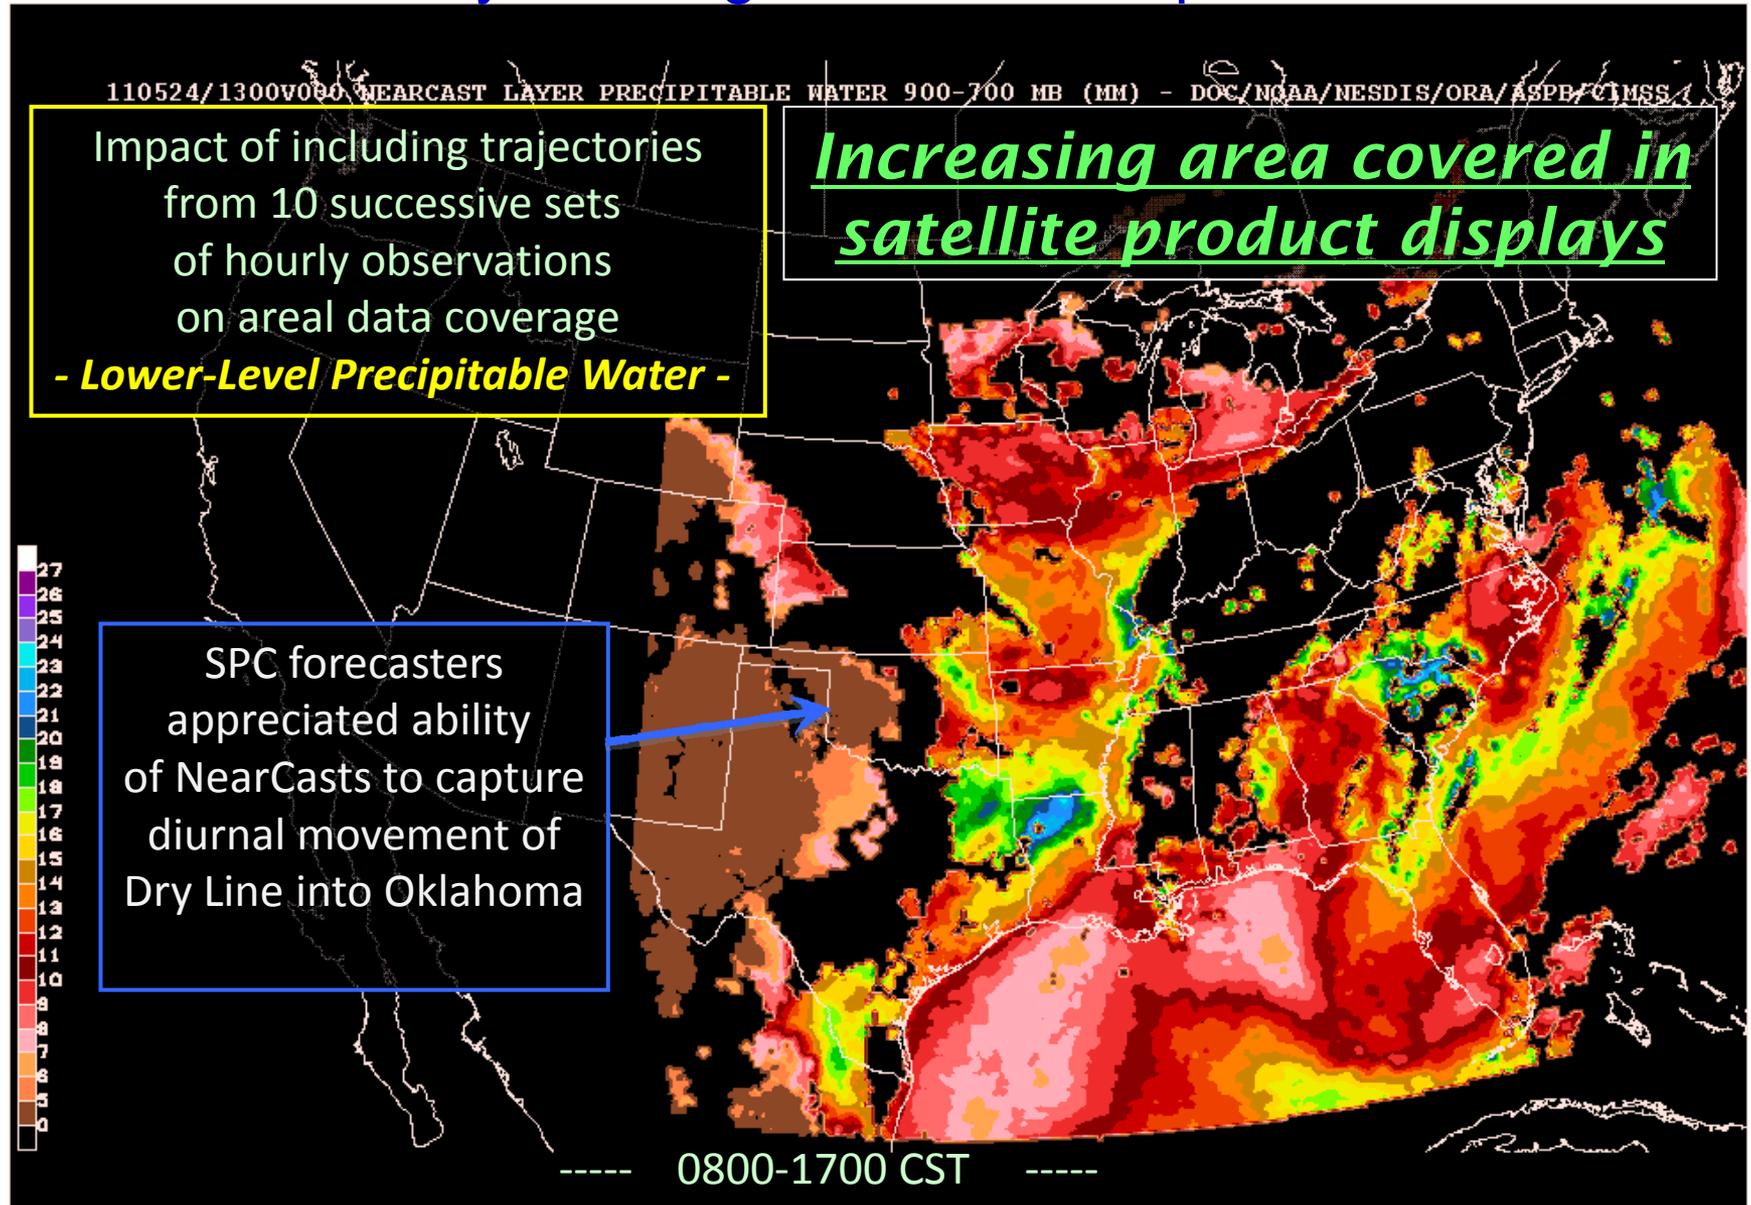

----- 1700 CDT -----

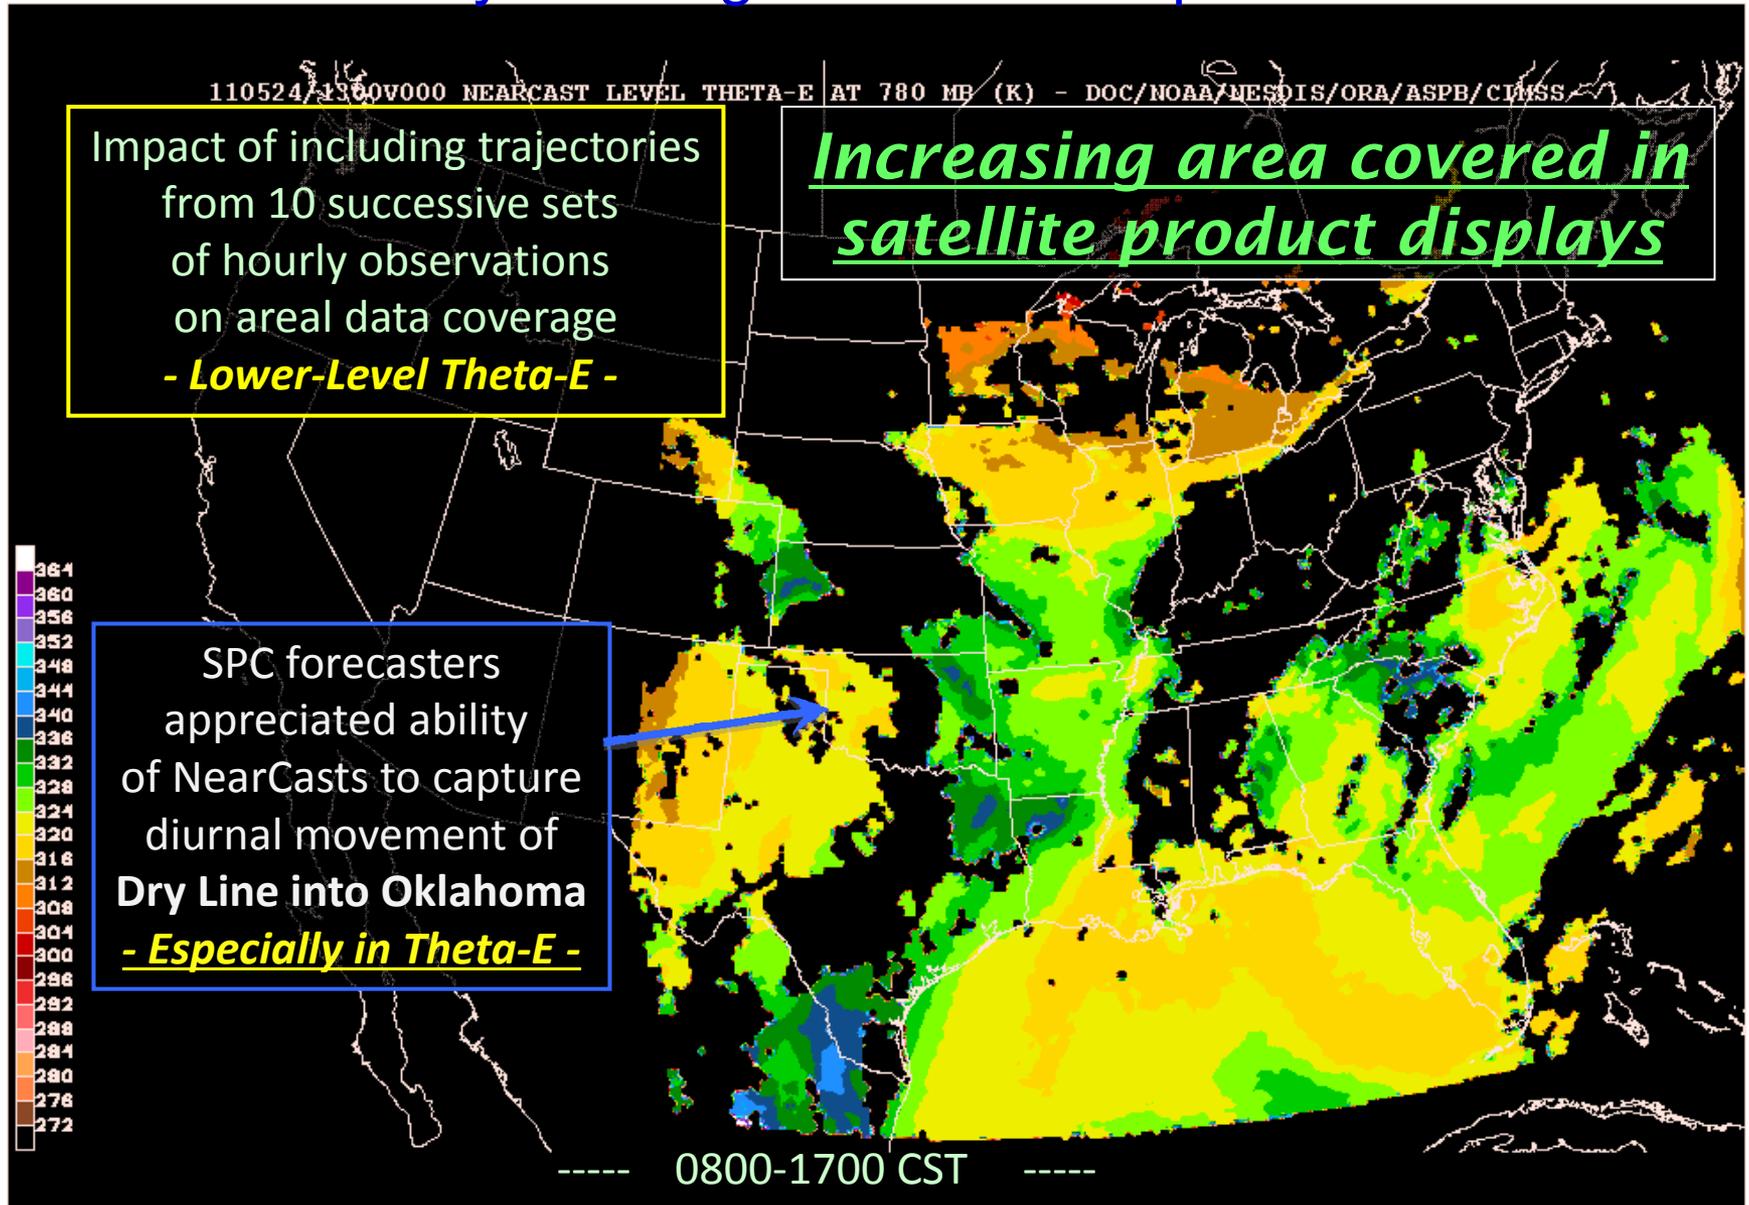

Combining 9 sets of "pseudo-observations" between 1300 and 2100UTC with GOES sounder observations at 2200UTC greatly shrinks data voids

# NearCast Analysis using "On-time" + 9 previous data sets

Combining 9 sets of "pseudo-observations" between 1300 and 2100UTC with GOES sounder observations at 2200UTC greatly shrinks data voids

# NearCast Analysis using "On-time" + 9 previous data sets

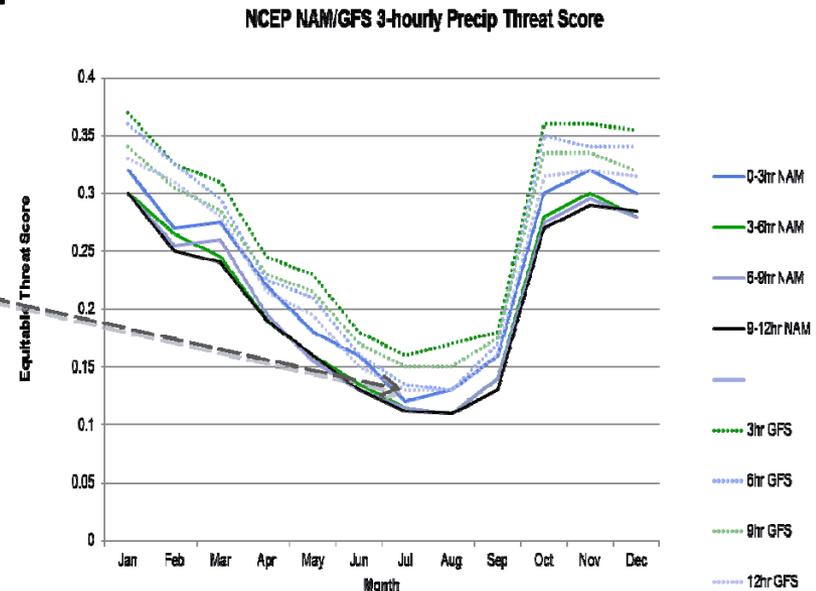

**Combining Lower-level Moisture and Temperature into Equivalent Potential Temperature ( $\theta_e$ ) improves depiction of total moist energy and stability**

# NearCasting evaluations comments included:

1. Provide information about dynamic triggering (*underway*)
2. Extend forecast length (*increased from 6 to 9 hours*)
3. Clouds limit the usefulness of product at times (*Extended analysis cycling using past data has helped*)
4. Nearcast fields (especially tendencies) were most useful when used to diagnose initial growth and coverage
5. Nearcasts most valuable when used in conjunction with observations and other model data (both where convection *will* and *will not* occur)

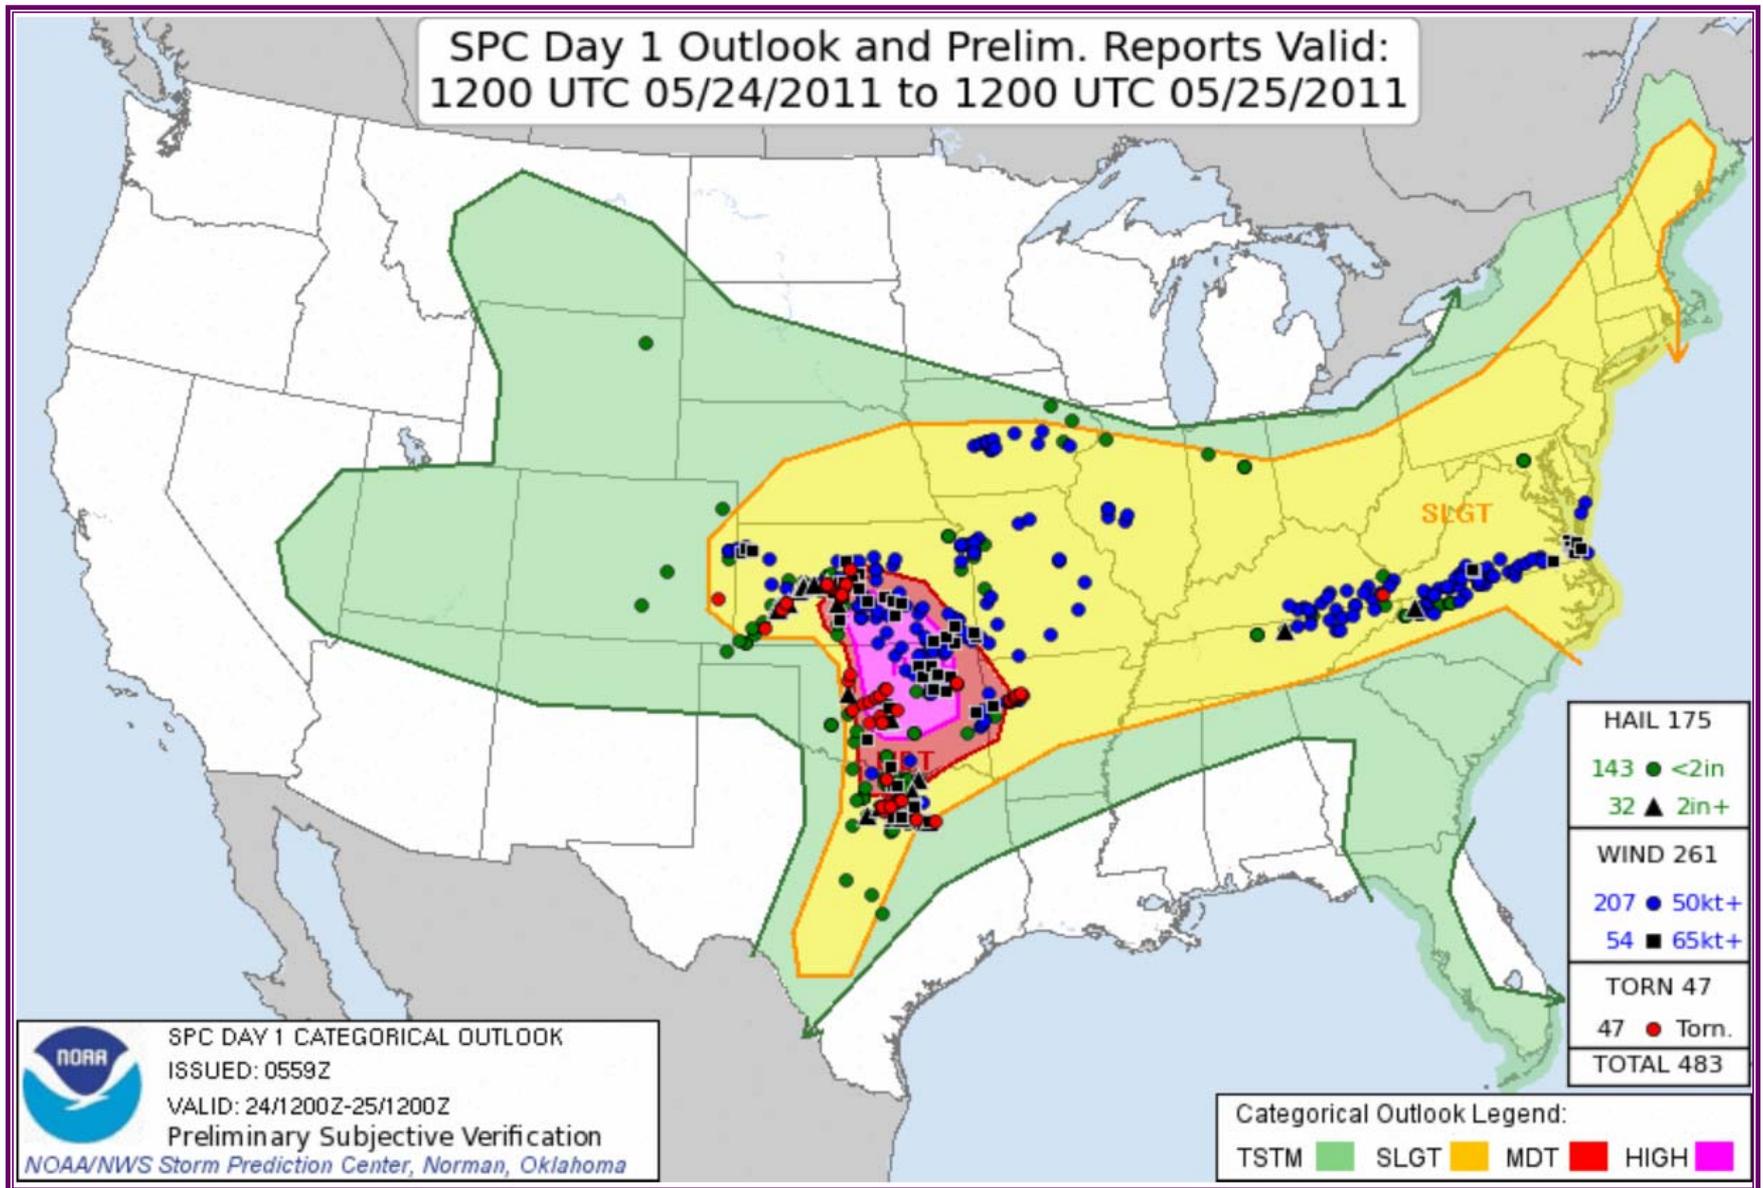

- Useful in updating/verifying NWP guidance
- Note: NWP correct only ~15% in summer

6. Forecasters need more experience using new products and help interpreting the observed fields & combined NearCast parameters

# Example from 24 May 2011

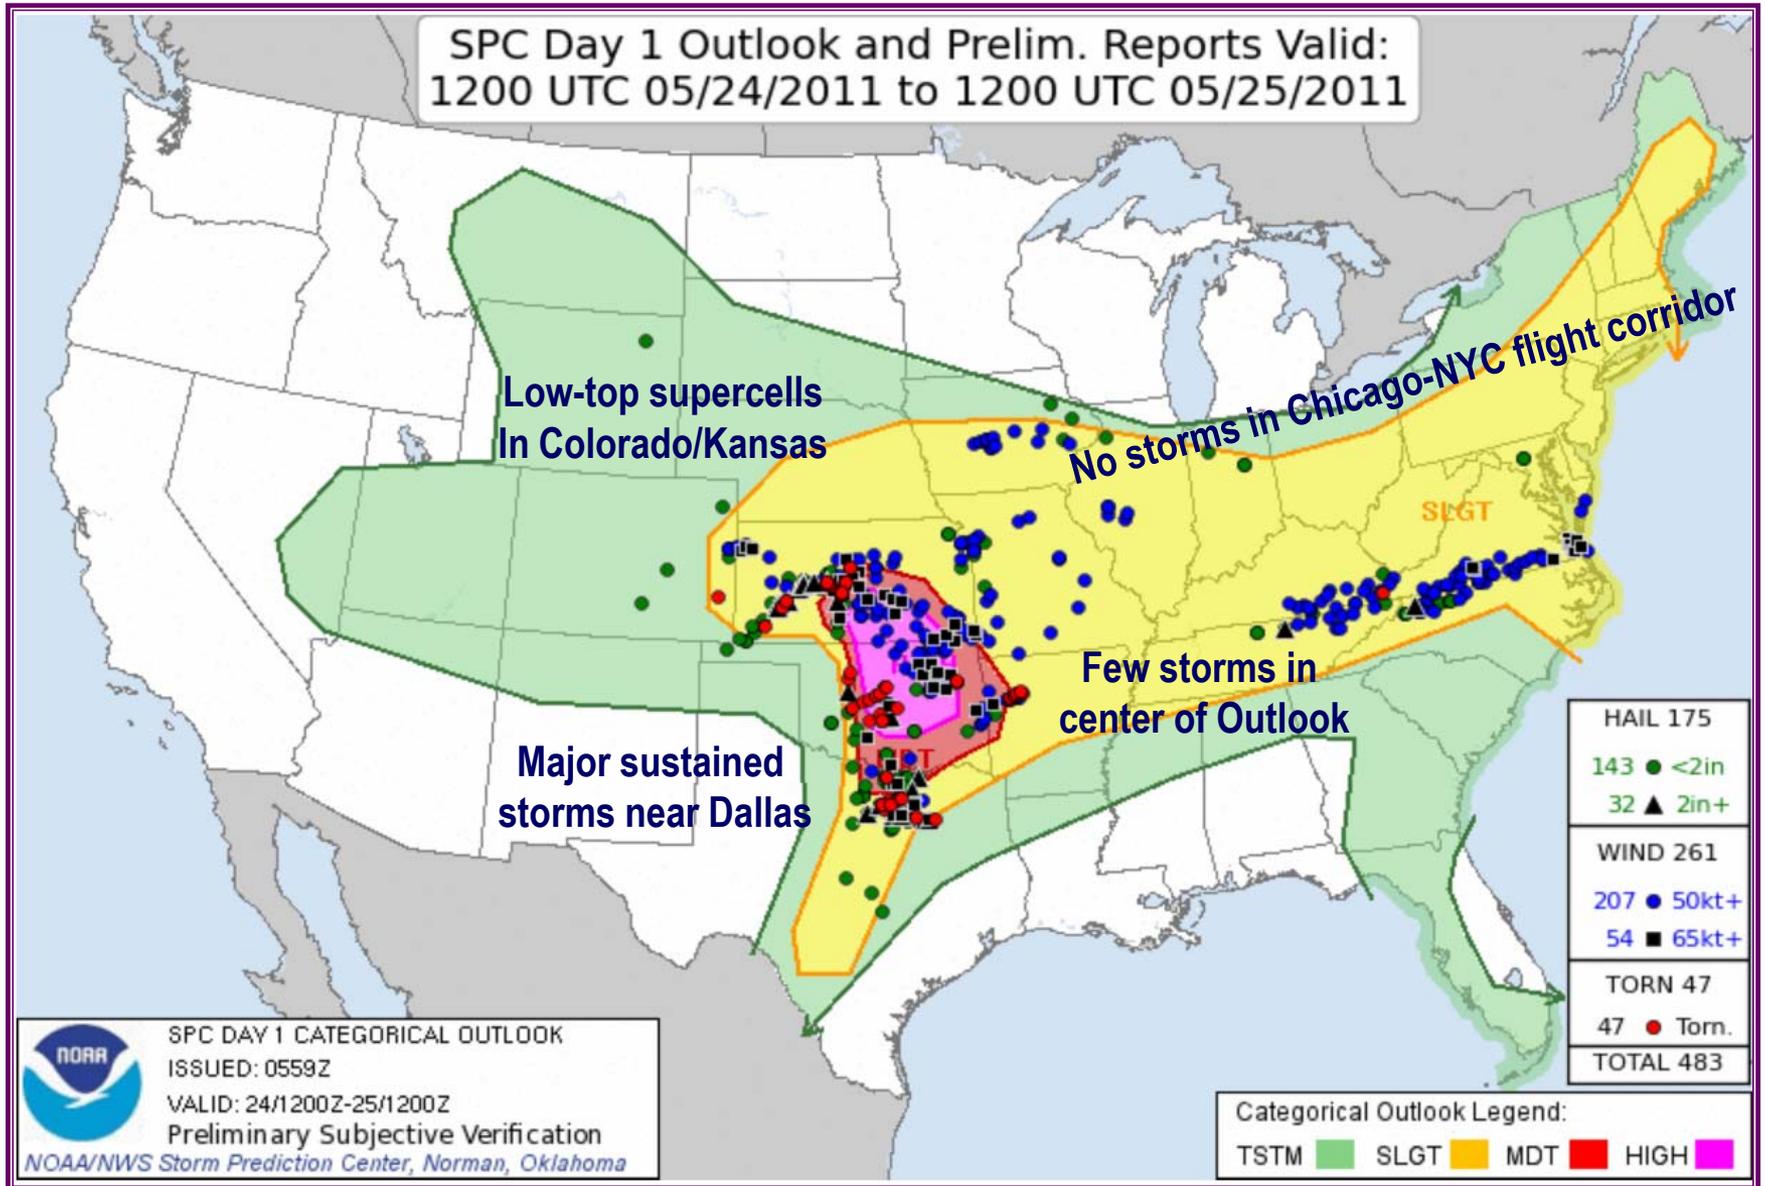

– Oklahoma Tornadoes – DFW Shutdown –

Generally good forecasts, but

# Example from 24 May 2011

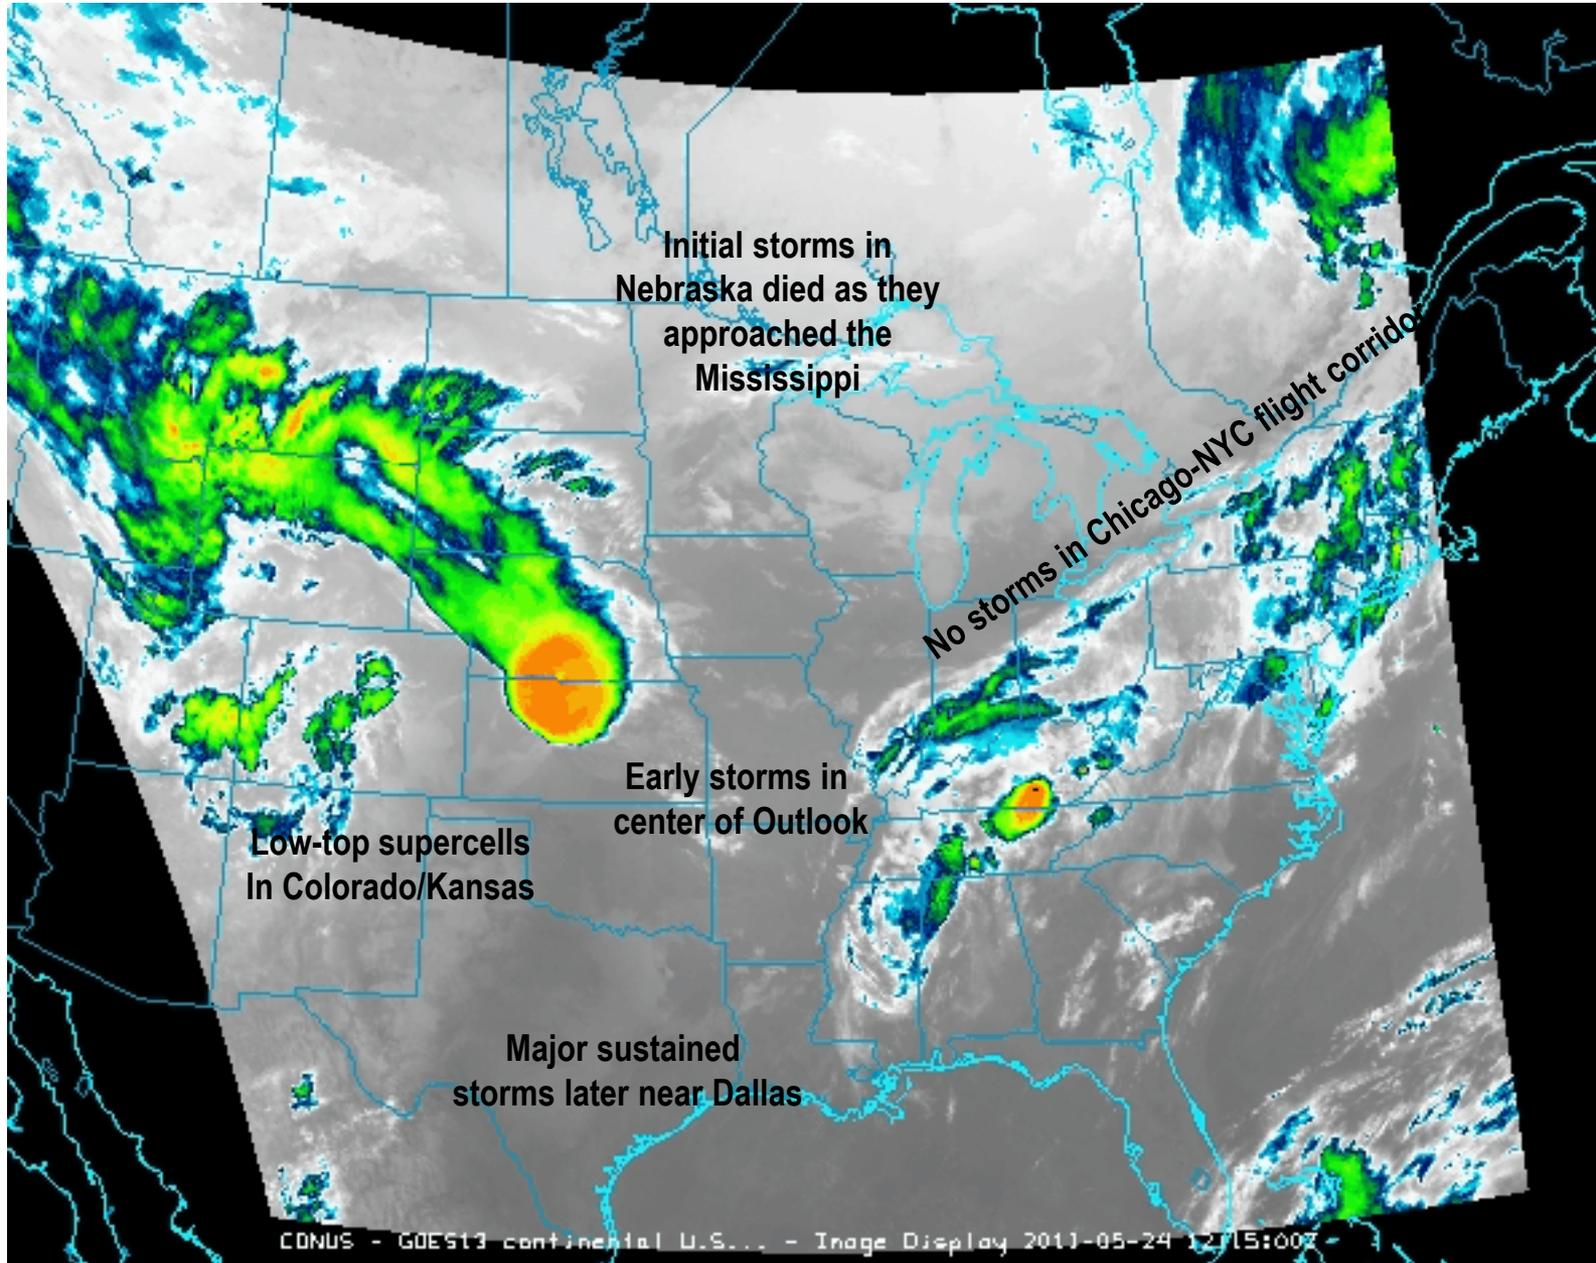

– Oklahoma Tornadoes – DFW Shutdown –

Generally good forecasts, but

# Example from 24 May 2011

- Oklahoma Tornadoes - DFW Shutdown -

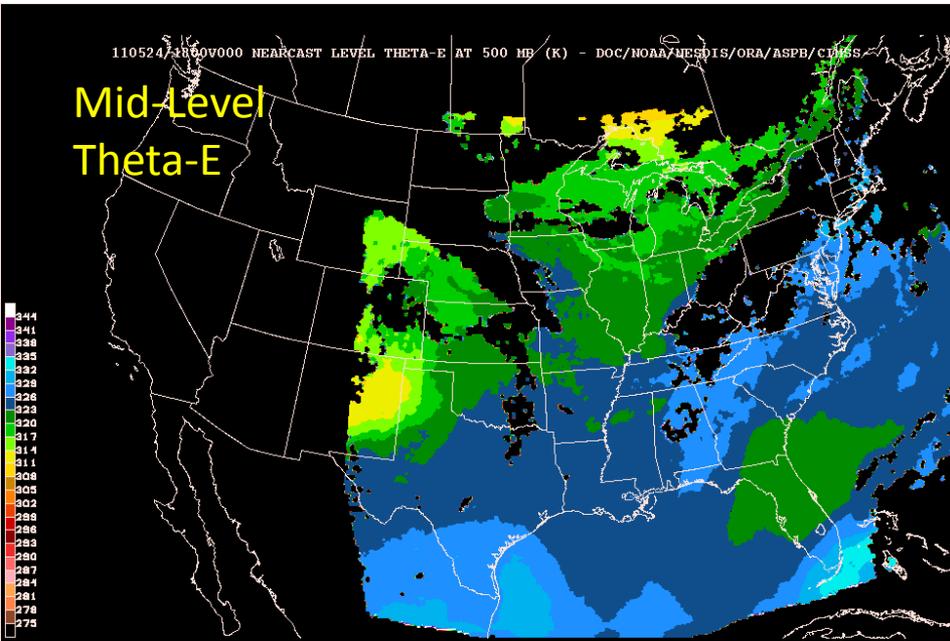

0 hours NearCasts from 1800 UTC 24 May 2011

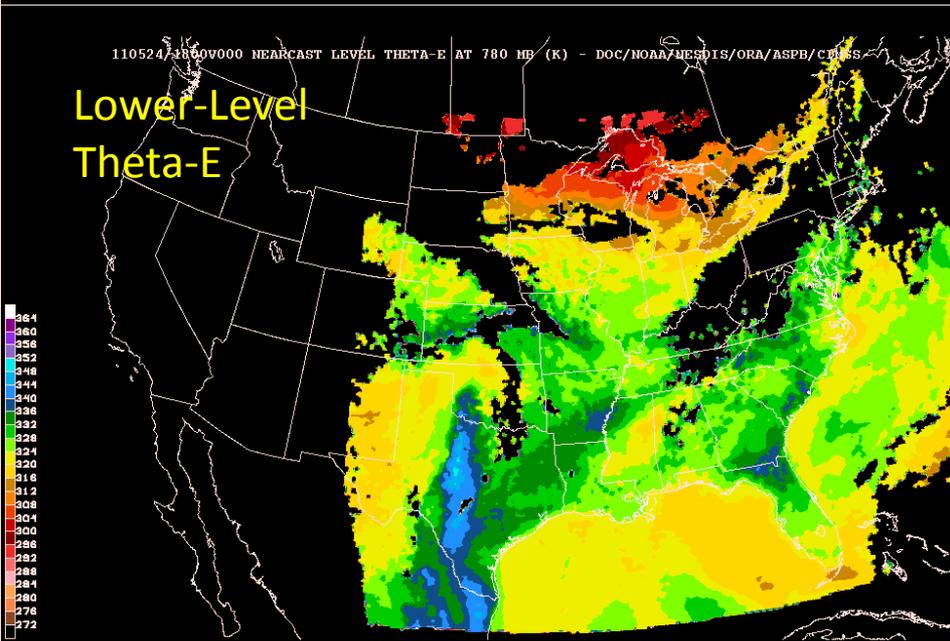

We will use Multiple-Parameter Displays that explain the physical processes producing Convective Instability

They are more useful than multiple sets of single parameter images  
Choice of color bars for display is critical

Mid-Level  
Theta-E

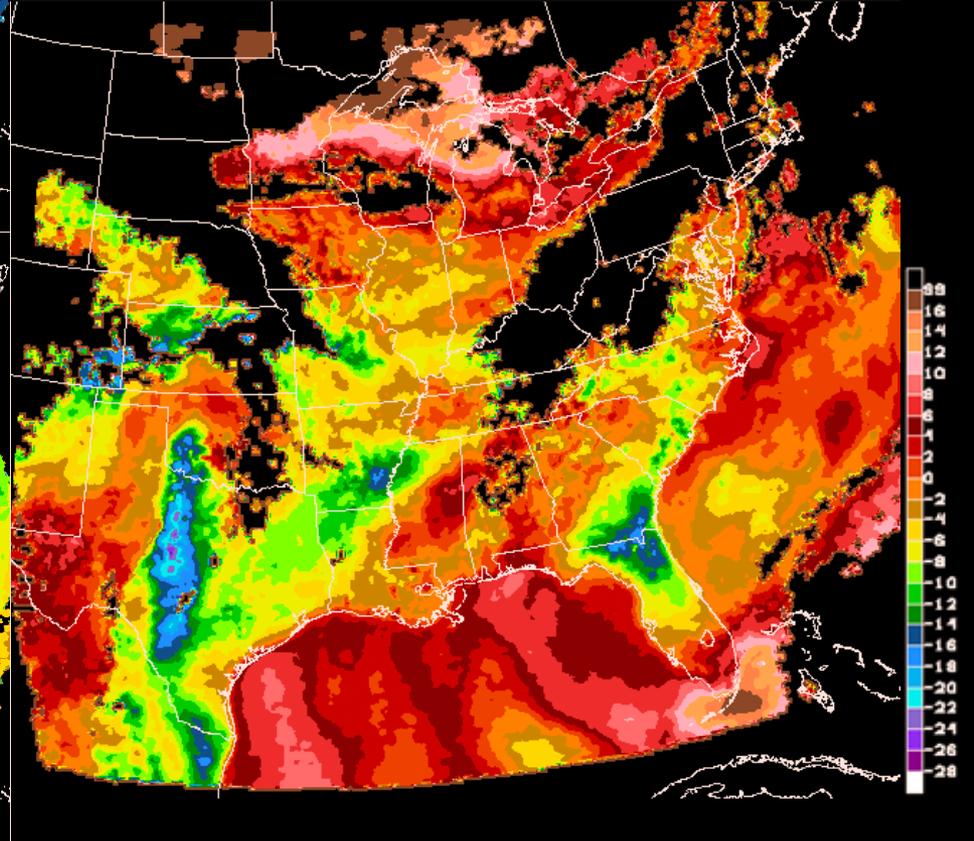

Lower-Level  
Theta-E

## CONVECTIVE INSTABILITY

Mid to Lower-level Theta-E Difference

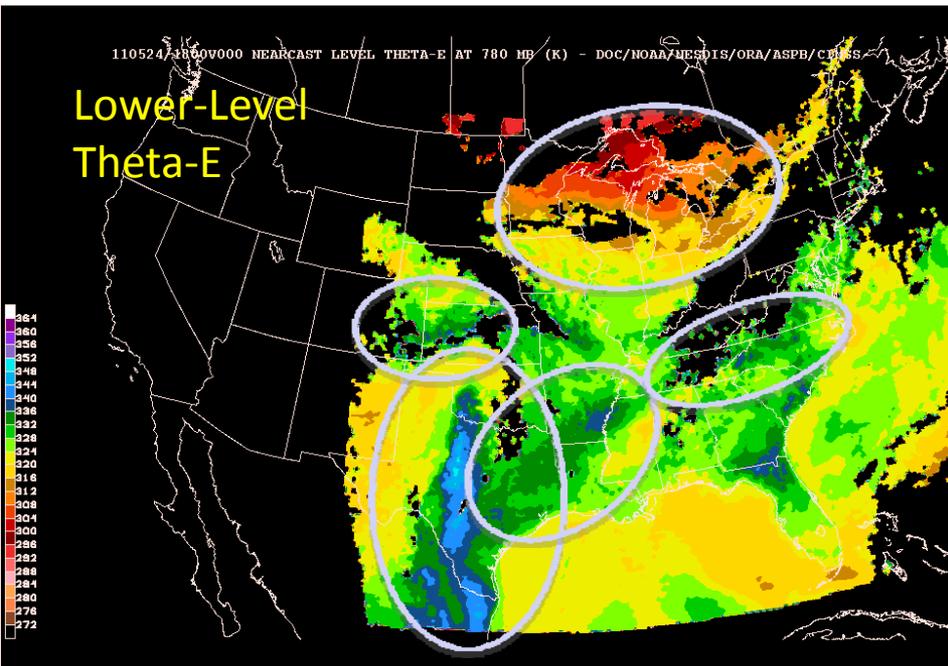

## 0 hour NearCasts from 1800 UTC 24 May 2011

Begin by examining the predicted evolution of  
Lower-Level  $\theta_e$  Fields.

These show the areas with the  
greatest total lower-level thermal energy

*At 1800 UTC, the Lower-Level  $\theta_e$   
NearCast Analysis shows:*

- 1) A north-south band of very moist/warm air extending across central Texas into far SW Oklahoma,
- 2) A secondary band of moderately high  $\theta_e$  across NE Texas into Arkansas,
- 3) A small area of enhanced  $\theta_e$  near the Virginia/North Carolina border,
- 4) An area of higher  $\theta_e$  surrounding a cloudy area in SE Colorado and western Kansas, and
- 5) An area of very low  $\theta_e$  over the upper Great Lakes and extending as far SE as Lakes Erie and Ontario

Begin by examining the predicted evolution of Lower-Level  $\theta_e$  Fields.

These show the areas with the greatest total lower-level thermal energy

The dynamical evolution of the Low-Level  $\theta_e$  structures in the various areas are especially apparent when the images are looped.

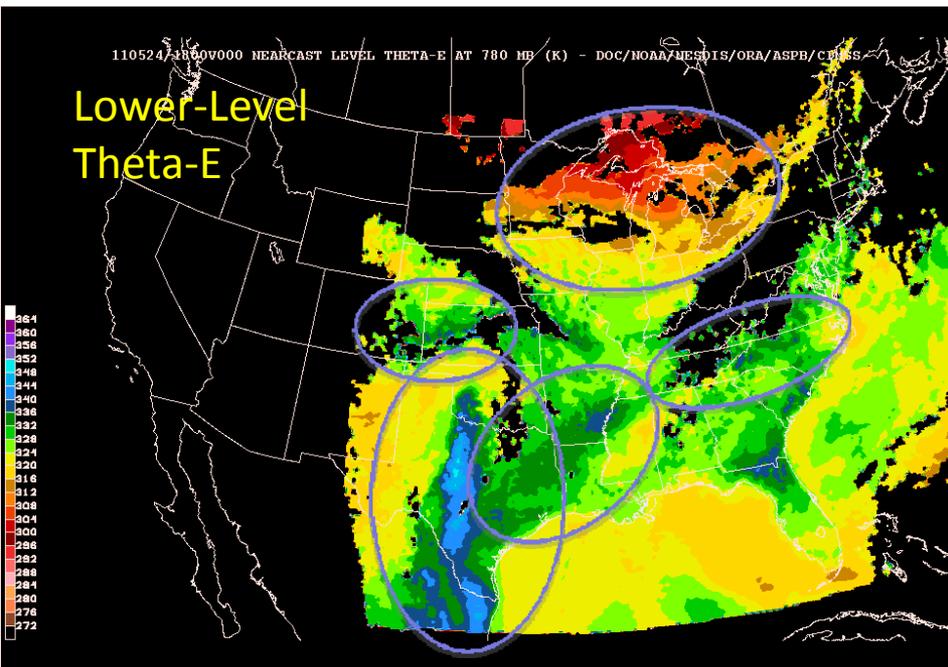

Lower-Level  $\theta_e$  NearCast Prediction shows:

1) The very moist/warm air initially from central Texas and SW Oklahoma shows a distinct maximum near Dallas and extending in an arc across central Oklahoma

2) The small area of higher  $\theta_e$  near the Virginia/North Carolina border continues to move slightly east,

3) The area of higher  $\theta_e$  in SE Colorado and western Kansas continues to rotate cyclonically, and

3) The area of low  $\theta_e$  over the upper Great Lakes reaches into central Pennsylvania.

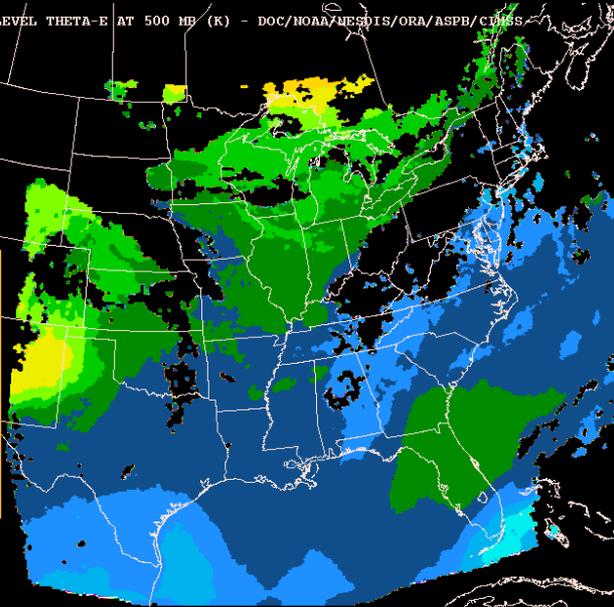

## 0-9 hours NearCasts from 1800 UTC 24 May 2011

### Mid-Level Theta-E

110524/2800000 NEARCAST LEVEL THETA-E AT 500 MB (K) - DOC/NOAA/NESDIS/ORA/ASPB/CISS

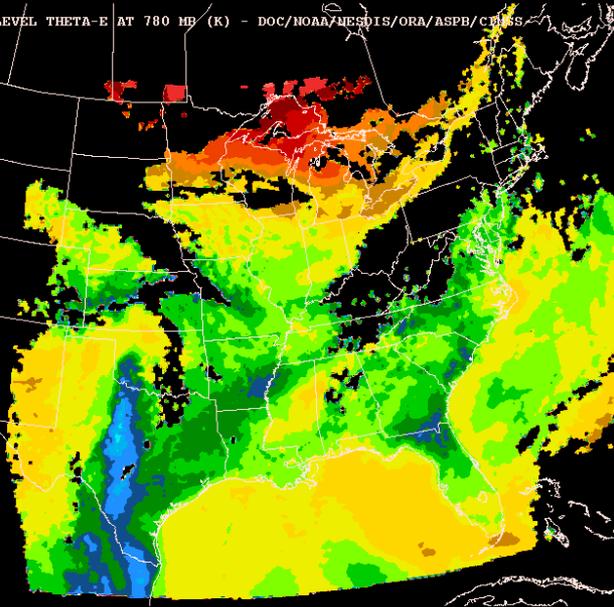

Note: This  
NearCast used  
data only from  
GOES

GOES West data  
can now also be  
used to expand  
coverage area.

### Lower-Level Theta-E

110524/2800000 NEARCAST LEVEL THETA-E AT 780 MB (K) - DOC/NOAA/NESDIS/ORA/ASPB/CISS

Next, examine the predicted evolution of  
Mid-Level  $\theta_e$  Fields.

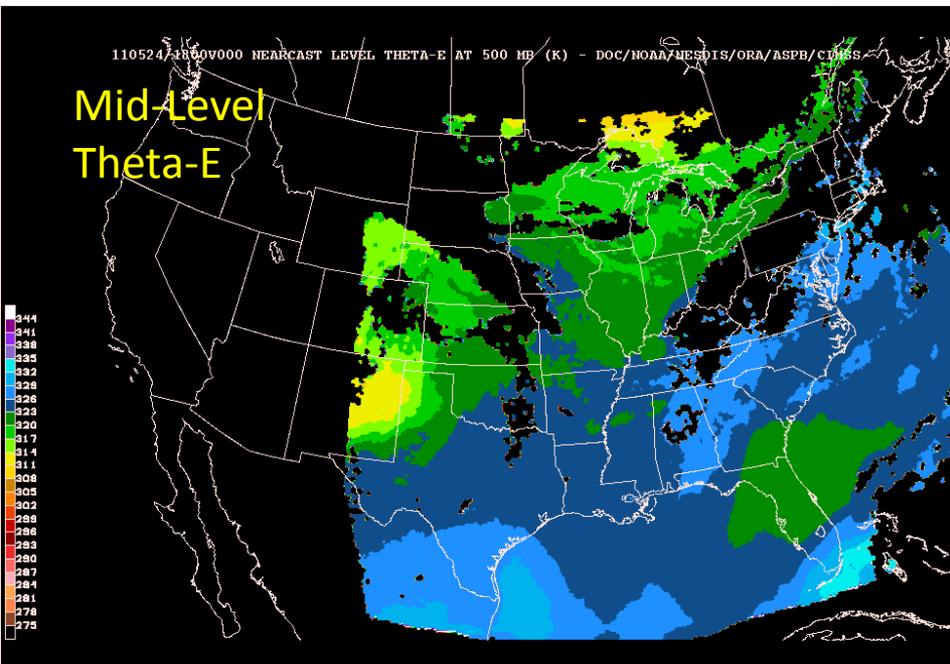

These show the areas Upper- and Mid-Level  
Dryness

Mid--Level  $\theta_e$  NearCast Prediction shows:

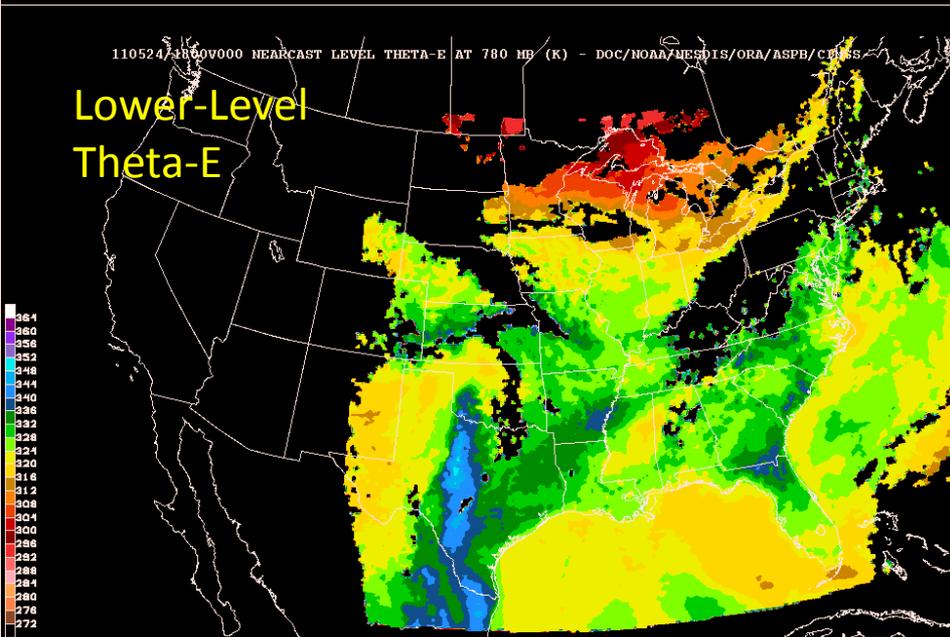

- 1) Dry air aloft, initially over New Mexico, moving from the west over the very moist/warm air initially from central Texas and SW Oklahoma due to differential advection,
- 2) Less dry air over the higher  $\theta_e$  near the Virginia/North Carolina border,
- 3) Dry air from Northern New Mexico rotating cyclonically over the higher  $\theta_e$  in SE Colorado and western Kansas, and
- 4) The dry/cool air (and low  $\theta_e$ ) over the upper Great Lakes extends through the full atmosphere.

0-9 hours NearCasts from 1800 UTC 24 May 2011

Mid-Level  
Theta-E

Lower-Level  
Theta-E

Combining information about local stability patterns using the predicted evolution of Low- and Mid-Level  $\theta_e$  Fields.

To better isolate that areas where differential advection is forcing upper-level dry/cool air to override lower-level warm/moist air, the two images on the left can be subtracted to create a depiction of the Deep-Layer Convective Instability.

This is equivalent to a Modified Lifted Index, where the stable/unstable threshold is shifted from  $0^\circ$  to  $-4^\circ$ .

GOES/SEVIRI observe this well !

In the following derived images, yellows, greens, blues and purples indicate increasingly unstable air.

Note: The Instability well only be released in areas where Low-level lifting is also present

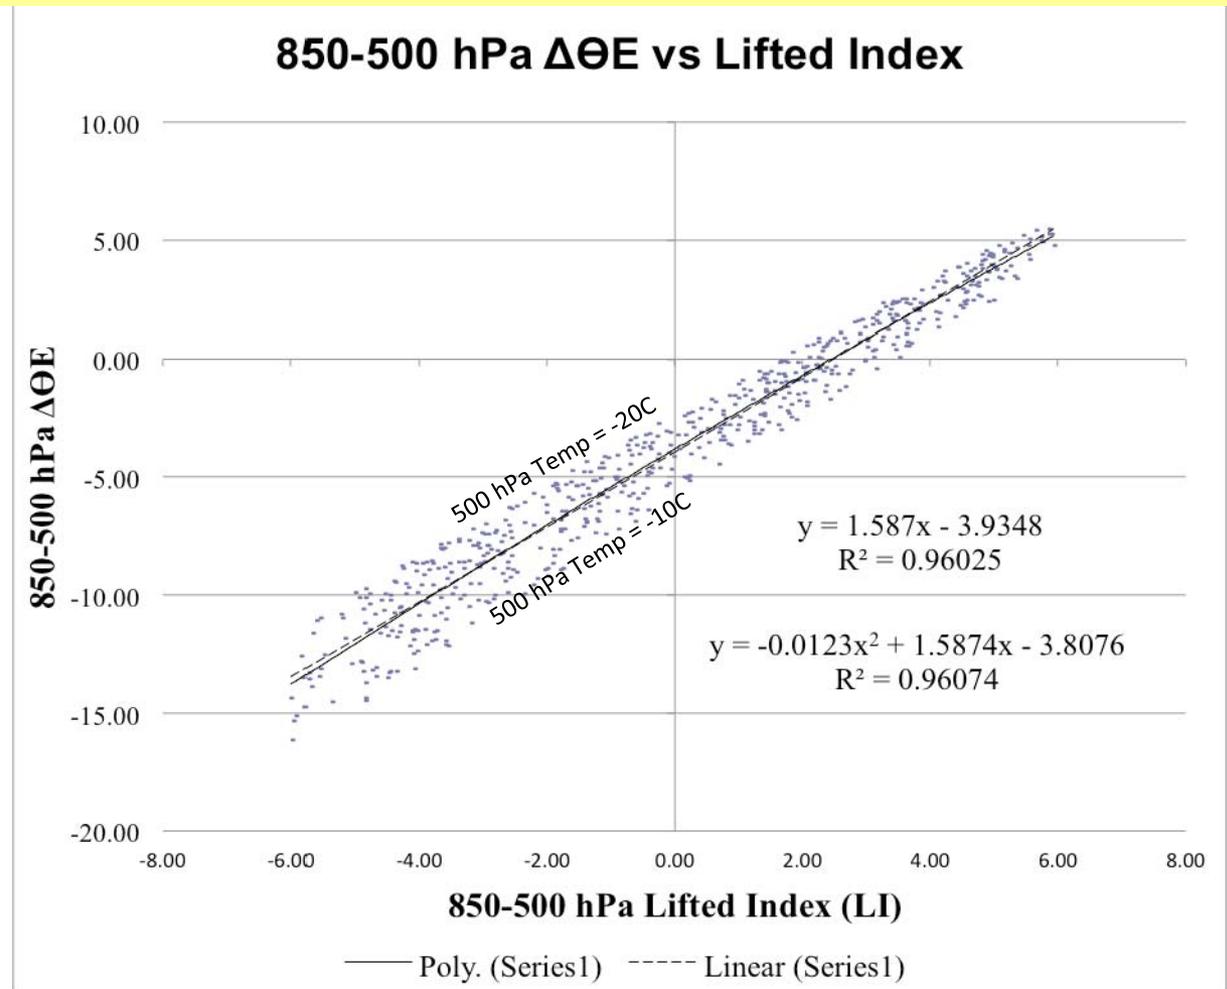

# Comparing Convective Instability to Lifted Index

Although imagery repeatedly shows that convection forms as dry air aloft overtakes areas of low-level moisture, confusion persists about the choice between Layer-based Convective Instability and Parcel-based Indices (e/g/, LI)

*Note:*

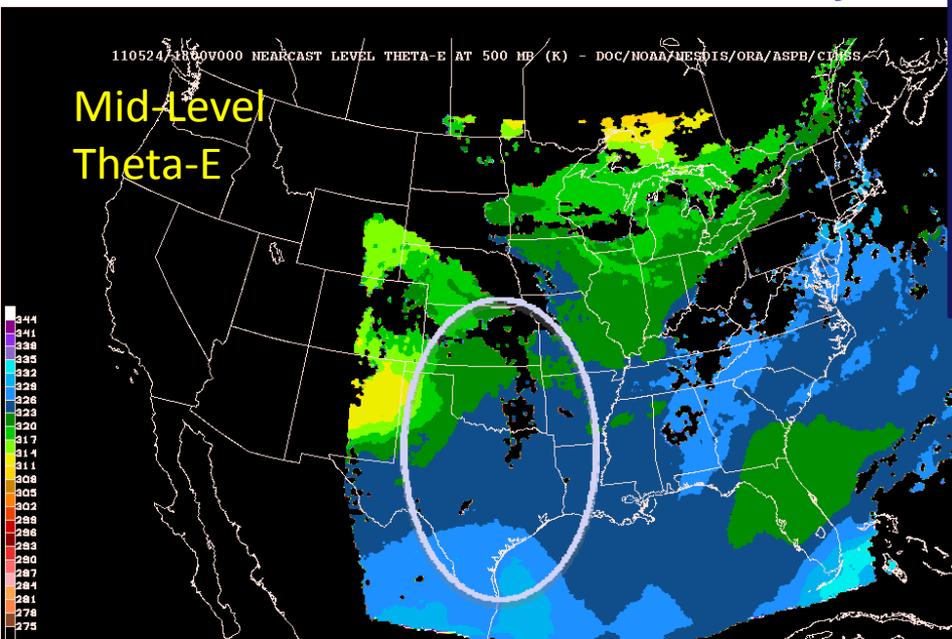

NearCasts determine  
Deep-layer  
Convective Instability  
from  $\partial\Theta e/\partial p$

Tests show that because ambient mid-level  $\theta_E$  and T are very similar, LI and Convective Instability are nearly equivalent and vary nearly linear, with ~3-4° offset, especially when the upper-layer is dry.

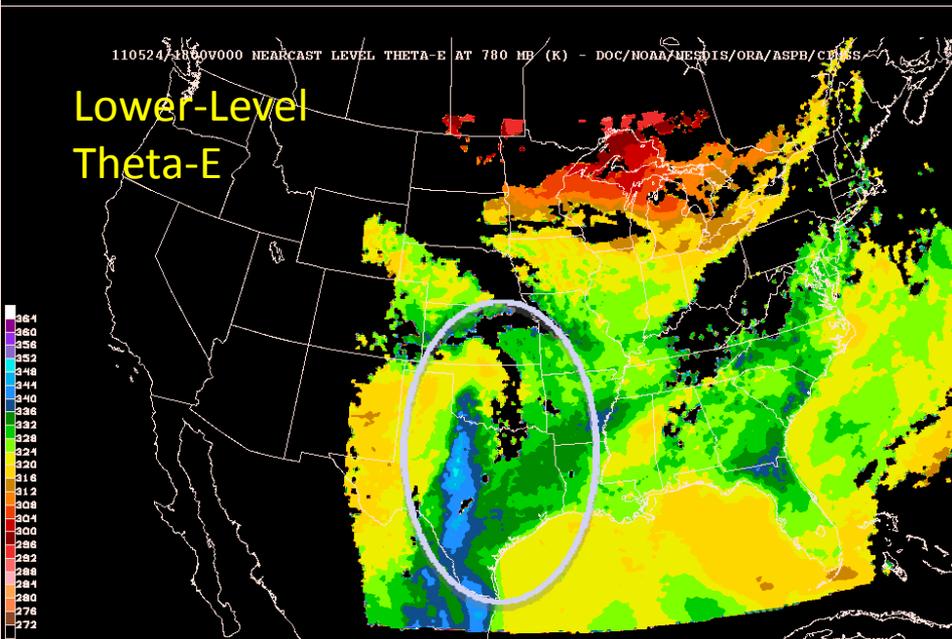

# 0-9 hours NearCasts from 1800 UTC 24 May 2011

## Mid-Level Theta-E

## Lower-Level Theta-E

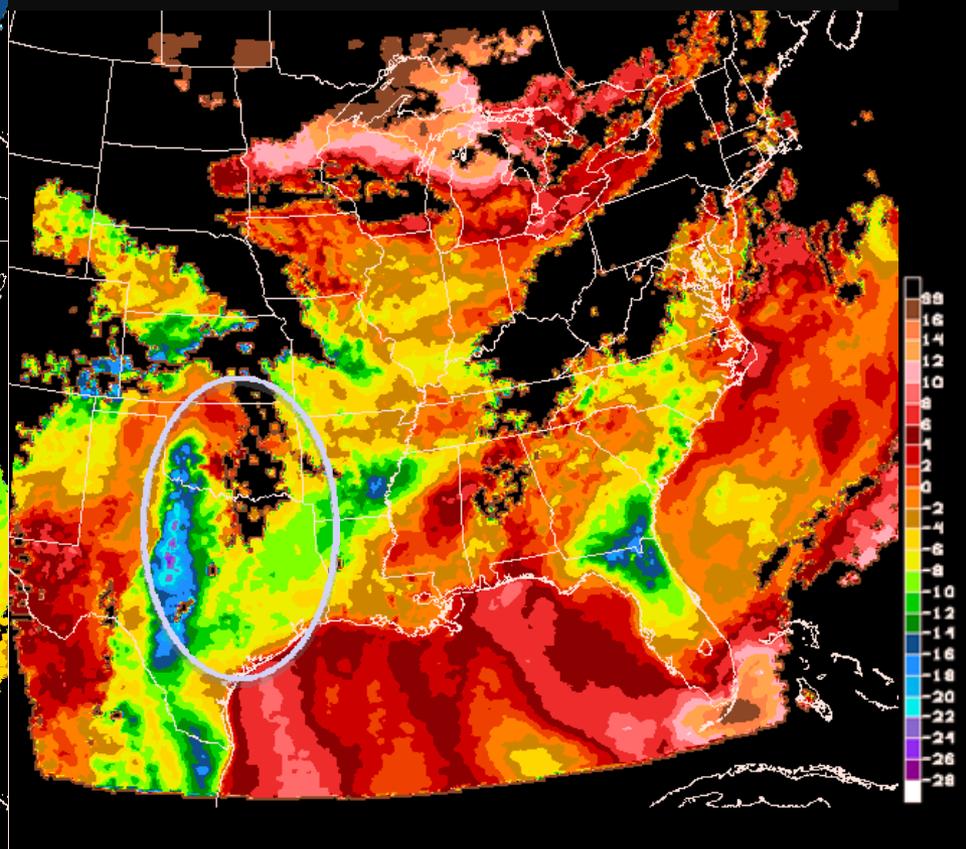

## Note:

- Instability moves first to central Oklahoma
- Instability increases, reaching Dallas later
- Instability intensifies over western Kansas near low-top super-cells
- Stable air from Great Lakes moves to cover most of Pennsylvania by end of end of period

## CONVECTIVE INSTABILITY

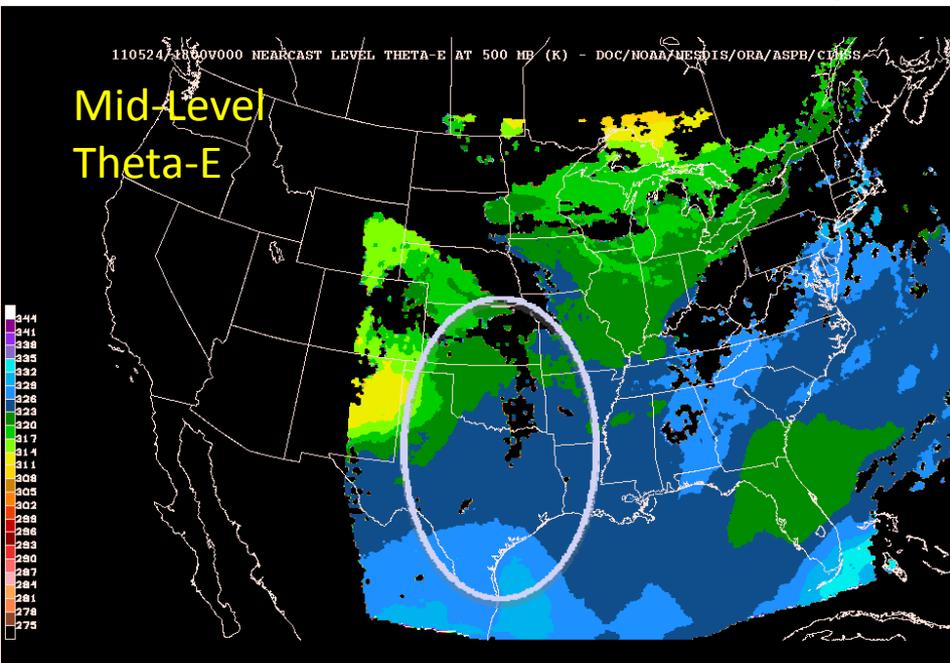

Mid to Lower-level Theta-E Difference

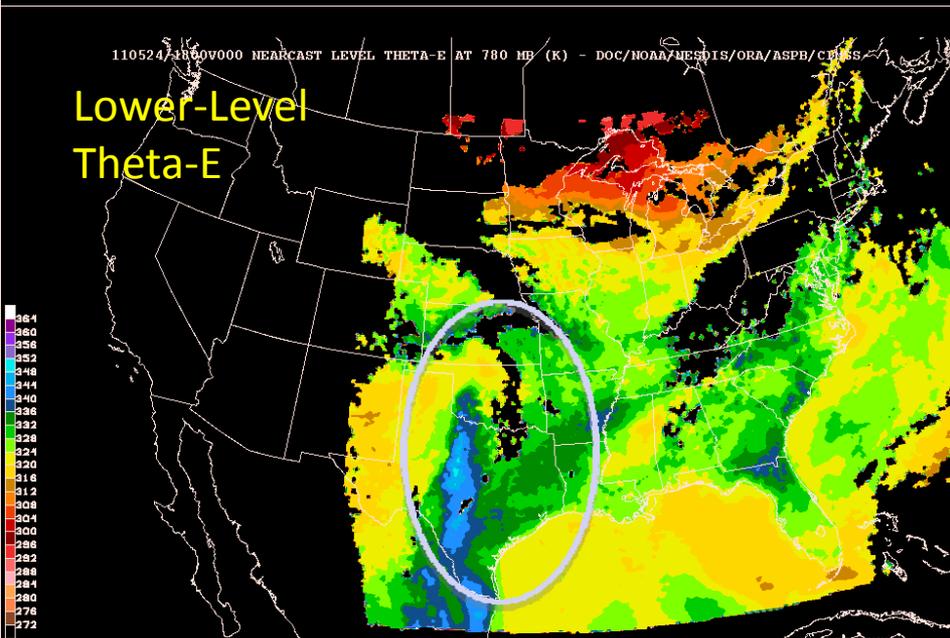

0-9 hours NearCasts from 1800 UTC 24 May 2011

Combining information about local stability patterns using the predicted evolution of Low- and Mid-Level  $\theta_e$  Fields.

Mid-Level  
Theta-E

Lower-Level  
Theta-E

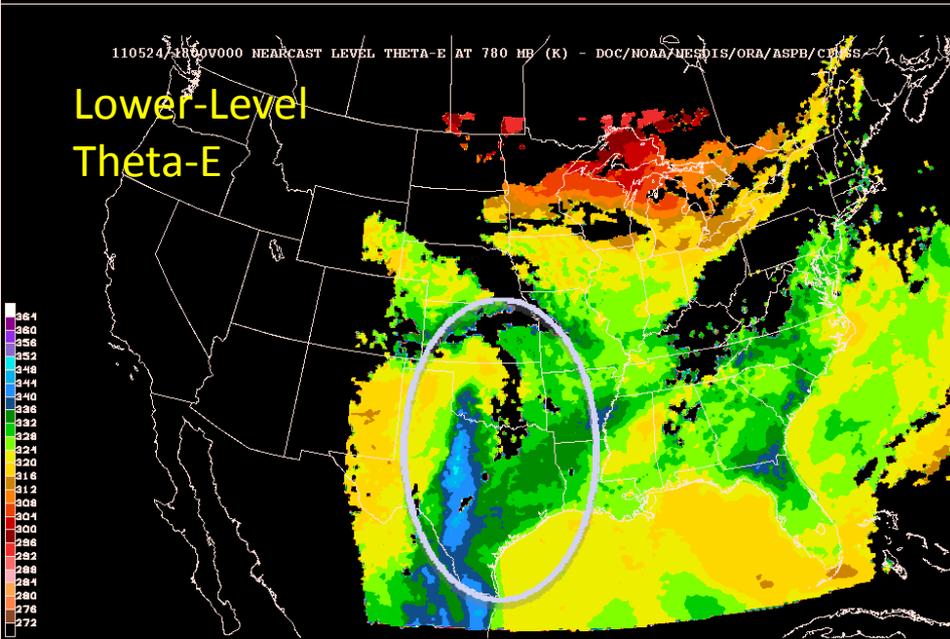

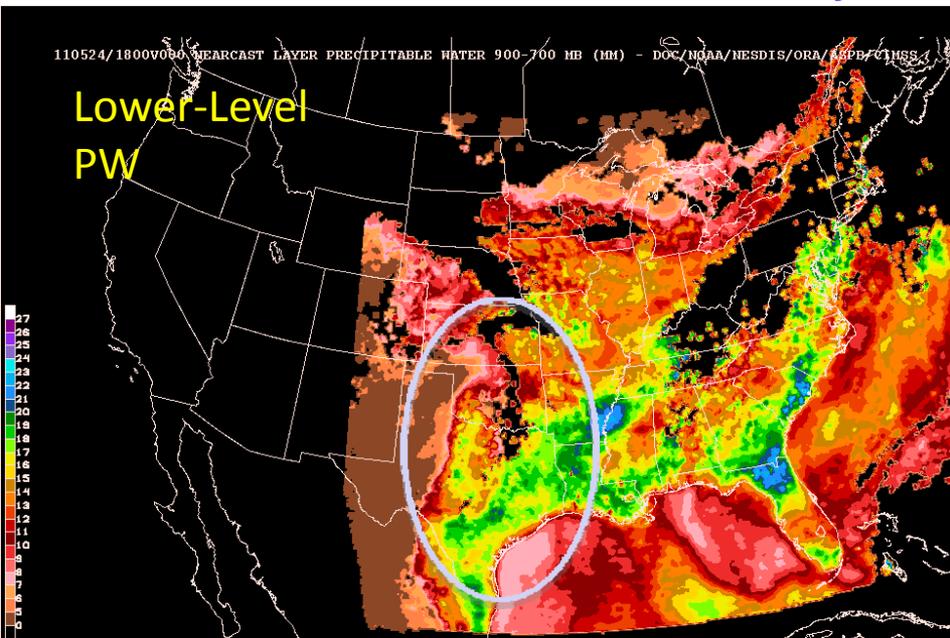

To better isolate areas where prolonged convection can be supported, an additional combination of NearCast outputs can be used to construct a “Long-Lived Convection Parameter”

This product of the Convective Instability, Low-Level  $\theta_e$  and Precipitable Water provides additional guidance as to both:

- 1) Where convection is likely to form rapidly, and
- 1) Where there is a large supply of warm and especially moist air already present to support continued growth of the storms

# 0-9 hours NearCasts from 1800 UTC 24 May 2011

Introduction of New Indices  
(e.g., a Long-Lived Convection Parameter that combines Conv. Instab., LI PW and  $\Theta_e$ ) was much easier when the 'Logic' for the Indices was included in the multi-parameter displays

## LONG-LIVED CONVECTION PARAMETER

Convective Instability \* Lower-Level THETA-E \* Lower-Level PW

Note: Only area indicating potential for formation of major sustained convection intensified and moved over Dallas at the time of prolonged storms
